# **Formula Syntax**

Formula editor is used in the following cases:

- Setting Column Formula
- Custom Fit Curve
- Cell editing in Table Editing

MagicPlot uses standard WIEEE 754 W double precision floating-point arithmetic. Double precision floating point takes 8 bytes per number and provides a relative precision of about 16 decimal digits and magnitude range from about  $10^{-308}$  to about  $10^{+308}$ .

### **Syntax Highlighting**

MagicPlot formula editor highlights expression syntax. It also marks matching brackets:

```
x = \$A;
a = 1.4499;
x0 = -1.232;
dx = 0.6936;
(a * exp(-ln(2) * (x-x0)^2 / dx^2))
+ (a * exp(-ln(2) * (x-(x0*-1))^2 / dx^2))
```

## **General Rules**

### **Case Sensitivity**

MagicPlot formula translator is generally **case sensitive**, i.e. you can write sin but not Sin.

Note that x and X are different variables. You can use this feature when naming curve parameters.

### **Entering Numbers**

You can use only dot (.) as decimal separator, e.g. 12.45. Comma (,) is used as function arguments separator, e.g. max(3.56,17.865).

You can use e or E for scientific notation: 1.45e-3 or 1.45E-3.

### **Using Spaces and Line Breaks**

You can freely insert space characters and line breaks in formula, but do not break function names, numbers, operators. You do not need to enter special characters to indicate line break.

## **Functions**

You can see a list of all available functions and their descriptions in *Functions* tab in *Set Column Formula* window.

MagicPlot uses functions of Java programming language library StrictMath to evaluate sin, cos, exp, etc. These functions are available from the well-known network library netlib as a "Freely Distributable Math Library", fdlibm package. The same library is widely used in many scientific computing applications.

## **Trigonometric Functions**

MagicPlot supports all standard trigonometric functions (sin, cos, etc.). All angles are always measured in radians for clarity.

You can use the following functions to convert angles units:

- deg(a) converts angles input in radians to an equivalent measure in degrees.
- rad(a) converts angles input in degrees to an equivalent measure in radians.

### **Examples**

- sin(rad(90))
- deg(asin(1))

### **Constants**

The predefined constants are:

- pi, Pi, Pi  $\pi$  = 3.1416... value (the ratio of circumference of a circle to its diameter).
- e e = 2.7183... value (the base of the natural logarithms). Note: expression e^a is evaluated as exp(a).
- nan, NaN, NAN Not-a-Number value.
- inf, Inf, infinity, Infinity positive infinity value which may be used in some calculations. **Note:** Write -inf for negative infinity.
- eps W machine epsilon, gives an upper bound of the relative error due to rounding in floating point arithmetic. **Note:** eps =  $ulp(1) = 2^{-52} = 2,2204E-16$ . (52 is the number of bits used to store fractional part of a number).

## **Boolean Logic**

MagicPlot can interpret boolean logic expressions. Zero and negative values (<=0) are interpreted as false and positive values (>0) are interpreted as true similarly to C programming language. You can use simple logical operators which are described below. Use 1 as true and 0 as false.

Sun Apr 28 16:52:16 2024 3/4 formula

#### 'if' Function

The basic logical function is if (condition, a, b). If condition argument is true (greater than 0) it returns the second argument (a), else returns the third argument (b).

#### **Examples**

- if(col(A) >= 0, col(A), -col(A)) evaluates absolute value of column A (certainly, you can use abs(col(A)) for that).
- if(col(B) >= 0, col(B), NaN) returns only positive values from column B. Negative values are replaced with NaN value (empty cell). You can use this expression to filter negative values if you do not want to use them in future calculations. Note that "Not-a-Number returned at row #" warning can be shown for such expression.
- if(col(A) > 0 & col(B) > 0, max(col(A), col(B)), NaN)

## **Equality Checking**

Generally, if you want to check equality of two values you need to use some equality threshold for relative difference. That is, you should compare the modulus of relative difference of two values a and b with threshold t: if(abs((a-b)/a) < t, ..., ...).

#### **Examples**

- sqrt(3)^2 3 results something about -4,4409E-16
- if(abs(sqrt(3)^2 3) / 3 < 1e-10, ..., ...) checks equality of sqrt(3)^2 and 3 with a threshold of 1e-10.

## **Operators**

Operator	Description	Operator	Description
+	addition	==	equal to
-	subtraction	!=	not equal to
*	multiplication	<	less than
/	division	>	greater than
^	power	<=	less than or equal to
1	or	>=	greater than or equal to
&	and		

## **Operations Priority**

Operators with **lower** precedence value are evaluated **earlier**. You can use brackets to change calculation sequence.

Expression is evaluated left-to-right, excluding repeated exponentiation operator  $^{\circ}$ . The  $^{\circ}$  operator is Wright-associative like in Fortran language (evaluated right-to-left; note that in general case  $a^{\circ}(b^{\circ}c) \neq (a^{\circ}b)^{\circ}c$ ). Hence  $a^{\circ}b^{\circ}c$  is evaluated as  $a^{\circ}(b^{\circ}c)$ .

The reason exponentiation is right-associative is that a repeated left-associative exponentiation operation would be less useful. Multiple appearances could (and would) be rewritten with multiplication:  $(a^b)^c = a^(b^*c)$ .

Operations	Precedence	Associativity
() (function call)	1	_
^	2	Right-to-left
- (unary minus)	3	_
*, /	4	Left-to-right
+, -	5	Left-to-right
<, >, <=, >=	6	Left-to-right
==, !=	7	Left-to-right
&	8	Left-to-right
	9	Left-to-right
= (assignment)	10	Left-to-right

### **Examples**

- 1 + 2 \* 3 returns 7.
- (1 + 2) \* 3 returns 9.
- 2\*-3 returns -6.
- -3^2 is equal to (3^2), because ^ priority is higher than that of unary minus. The result is -9.
- (-3)^2 returns 9.
- 2^2^3 is equal to 2^(2^3), because ^ is right-associative operator. The result is 256.
